# Atomic execution

# Atomic execution

# Registers

- ☞ **Question 1:** what objects can we implement with registers? (this lecture)
- ☞ Question 2: what objects we cannot implement? (next lecture)

# Wait-free implementations of atomic objects

- ➊ An ***atomic*** object is simply defined by its sequential specification; i.e., by how its operations should be implemented when there is no concurrency
- ➋ Implementations should be ***wait-free***: every process that invokes an operation eventually gets a reply (unless the process crashes)

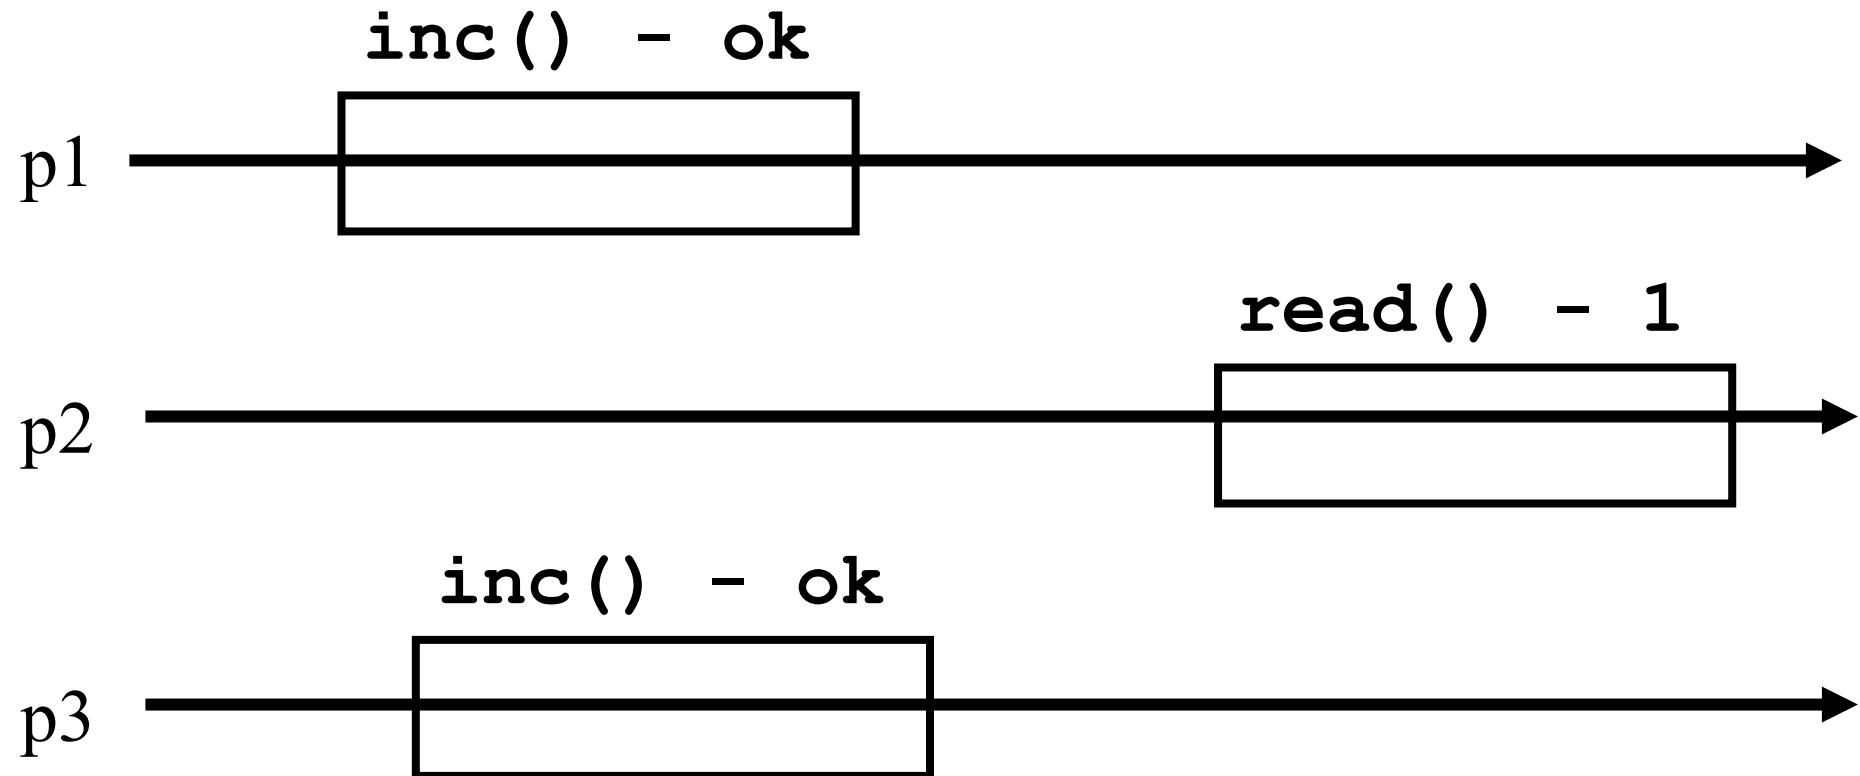

# Counter (sequential spec)

- ➊ A **counter** has two operations ***inc()*** and ***read()*** and maintains an integer  $x$  *init to 0*
  
- ➋ ***read():***
  - ➌ `return(x)`
  
- ➌ ***inc():***
  - ➌ `x := x + 1;`
  - ➌ `return(ok)`

# Naive implementation

- ☛ The processes share one register **Reg**
- ☛ ***read()*:**
  - ☛ return(Reg.read())
- ☛ ***inc()*:**
  - ☛ temp:= Reg.read()+1;
  - ☛ Reg.write(temp);
  - ☛ return(ok)

# Atomic execution?

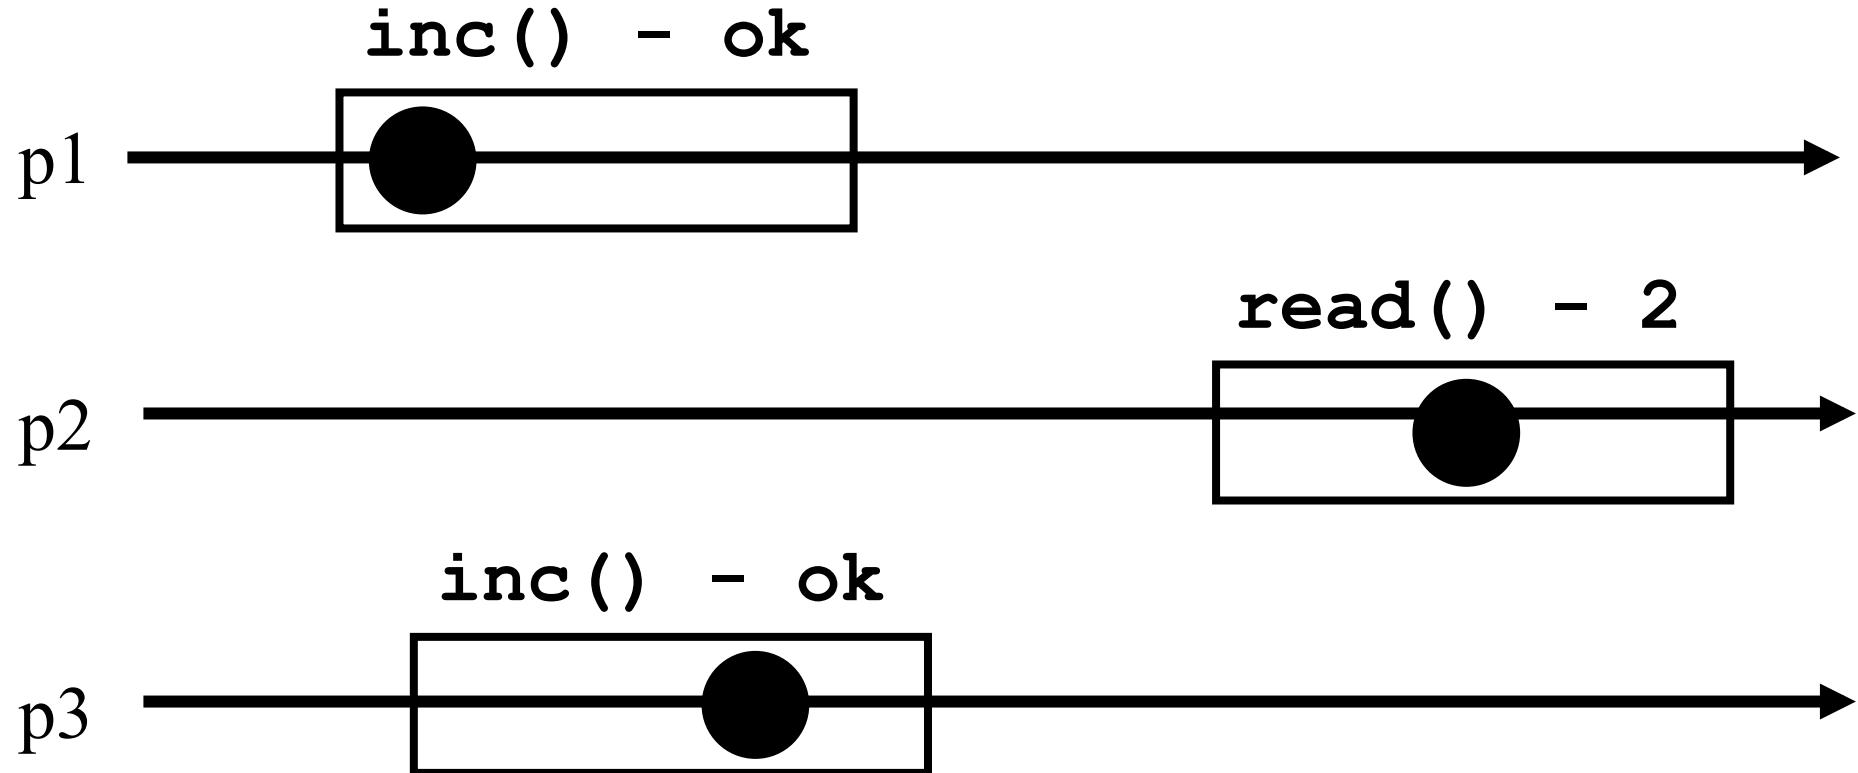

# Atomic implementation

- ☞ The processes share an array of registers  
Reg[1,..,n]
- ☞ *inc():*
  - ☞ temp := Reg[i].read() +1;
  - ☞ Reg[i].write(temp);
  - ☞ return(ok)

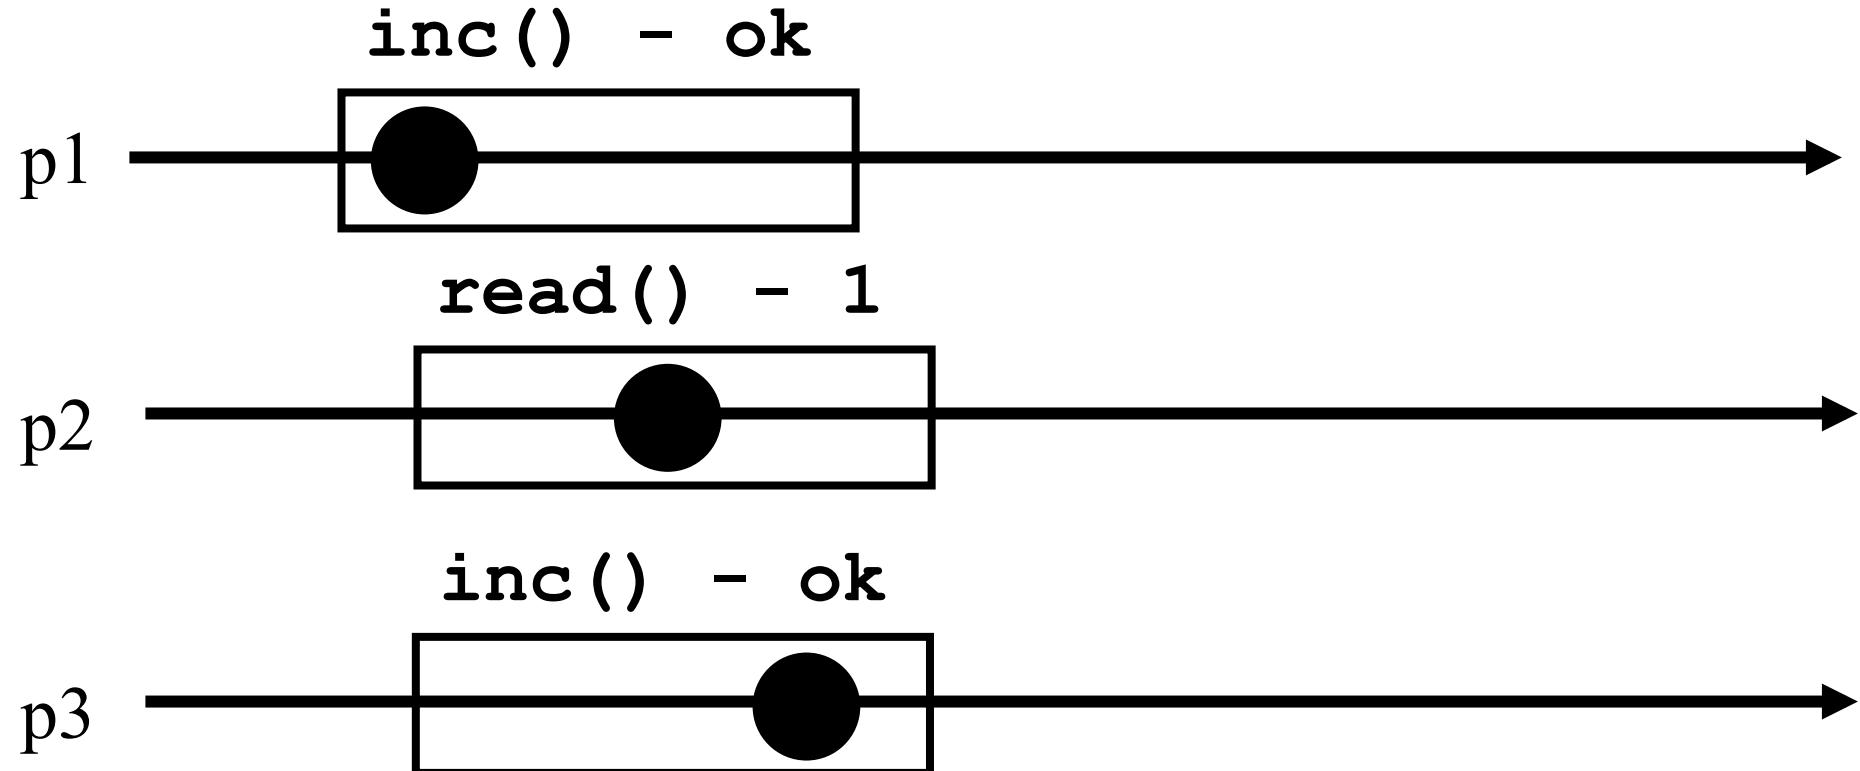

# Atomic implementation

```
☛ read():
    ☛ sum := 0;
    ☛ for j = 1 to n do
        ☛     sum := sum + Reg[j].read();
    ☛ return(sum)
```

# Atomic execution?

# Atomic execution?

# Better atomic implementation

- ☞ The processes share an array of registers  
Reg[1,..,n]
- ☞ *inc():*
  - ☞ value := value +1;
  - ☞ Reg[i].write(value);
  - ☞ return(ok)

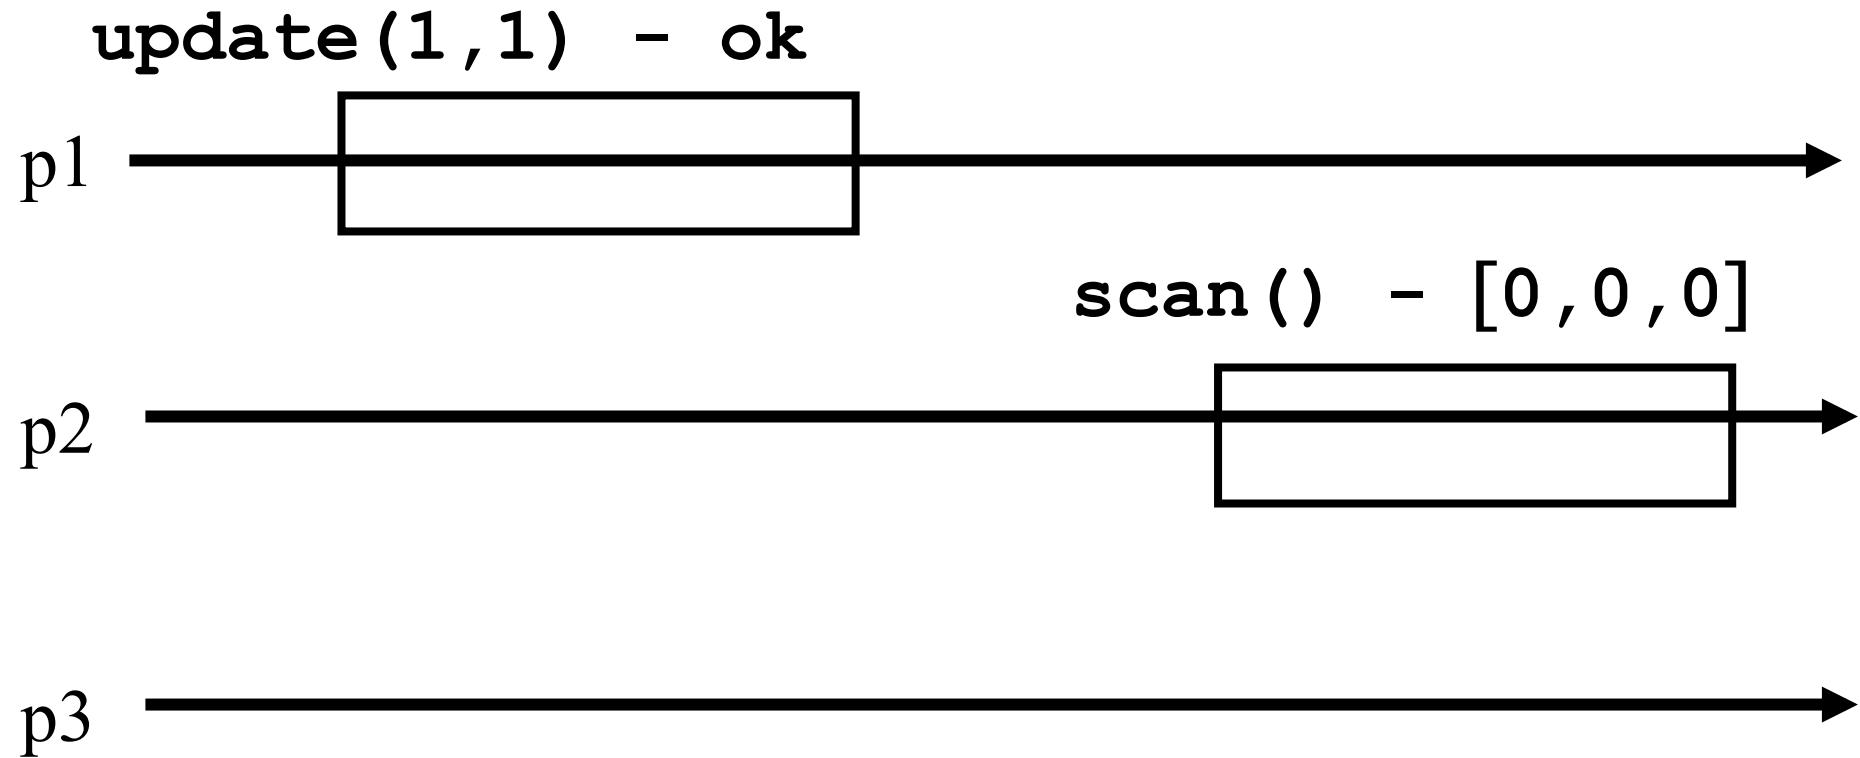

# Snapshot (sequential spec)

- ➊ A ***snapshot*** has operations ***update()*** and ***scan()***; it maintains an array  $x$  of size  $n$
  
- ➋ ***scan():***
  - ➌ `return(x)`
  
- ➌ ***update( $i, v$ ):***
  - ➌  `$x[i] := v;$`
  - ➌ `return(ok)`

# Very naive implementation

- ☛ Each process maintains an array of integer variables  $x$  init to  $[0,..,0]$
- ☛ ***scan():***
  - ☛ `return(x)`
- ☛ ***update(i,v):***
  - ☛ `x[i] := v;`
  - ☛ `return(ok)`

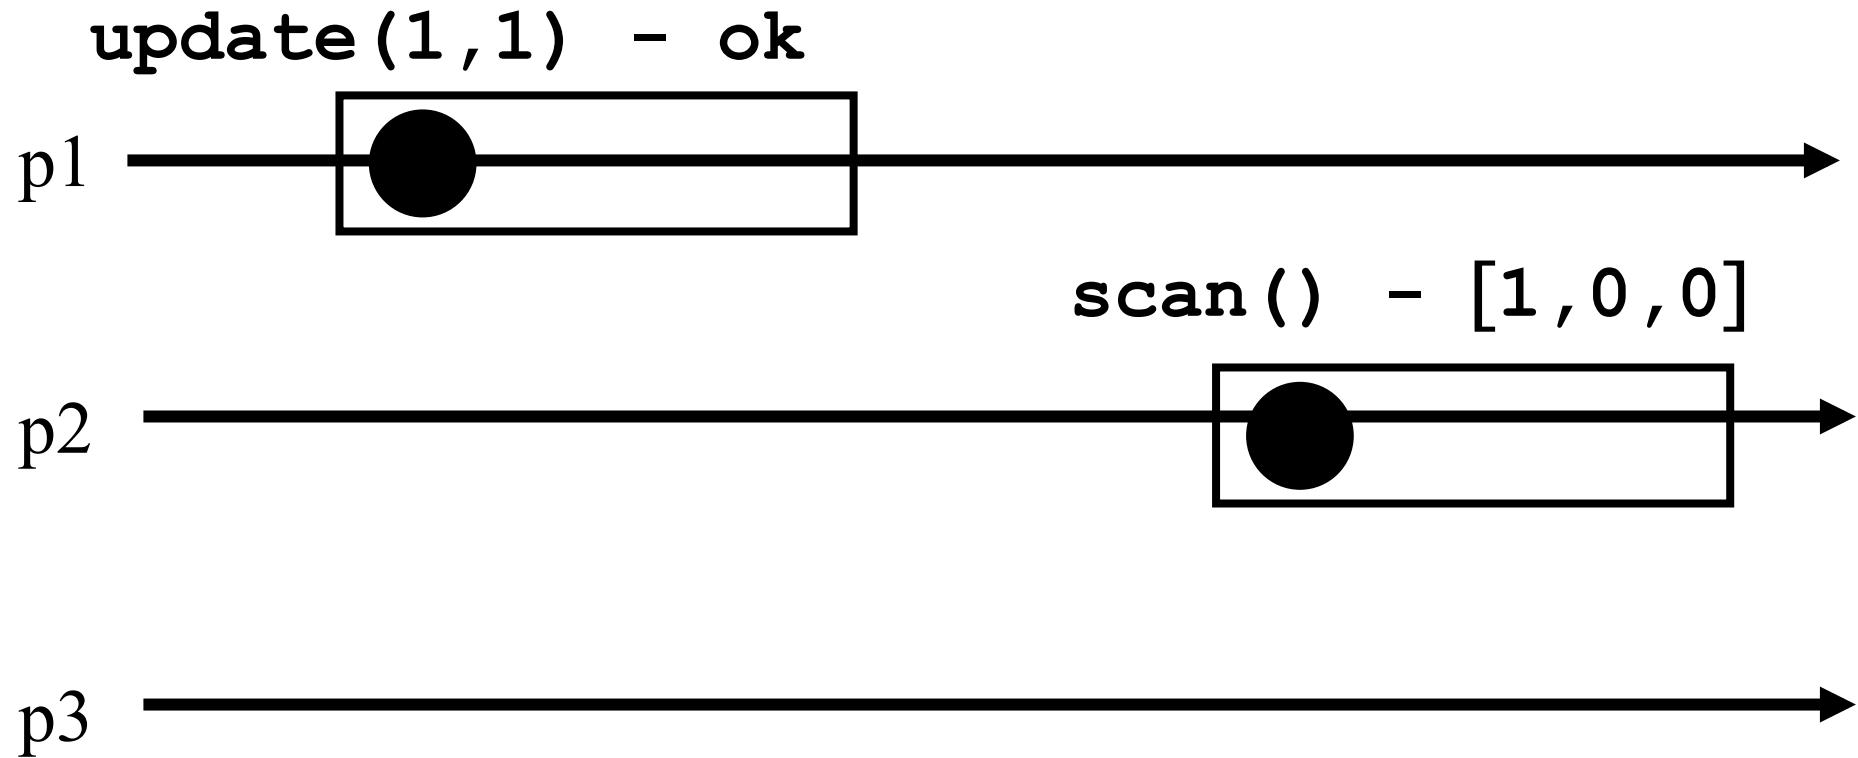

# Atomic execution?

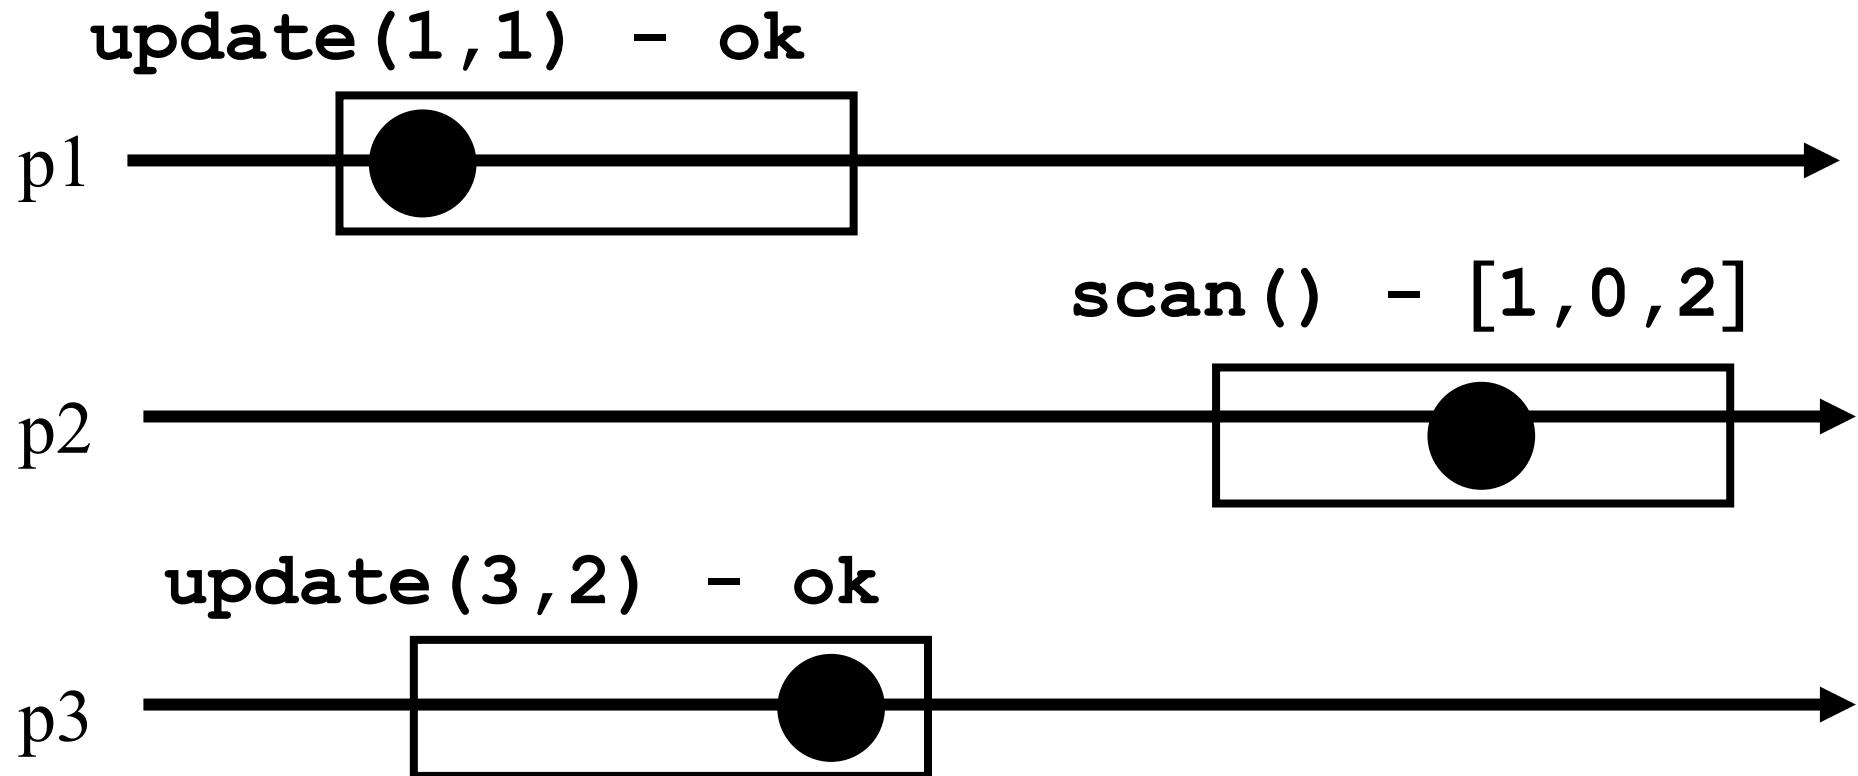

# Less naive implementation

- ☛ The processes share one array of N registers  
Reg[1,...,N]
- ☛ ***scan():***
  - ☛ for j = 1 to N do
    - ☛ x[j] := Reg[j].read();
  - ☛ return(x)
- ☛ ***update(i,v):***
  - ☛ Reg[i].write(v); return(ok)

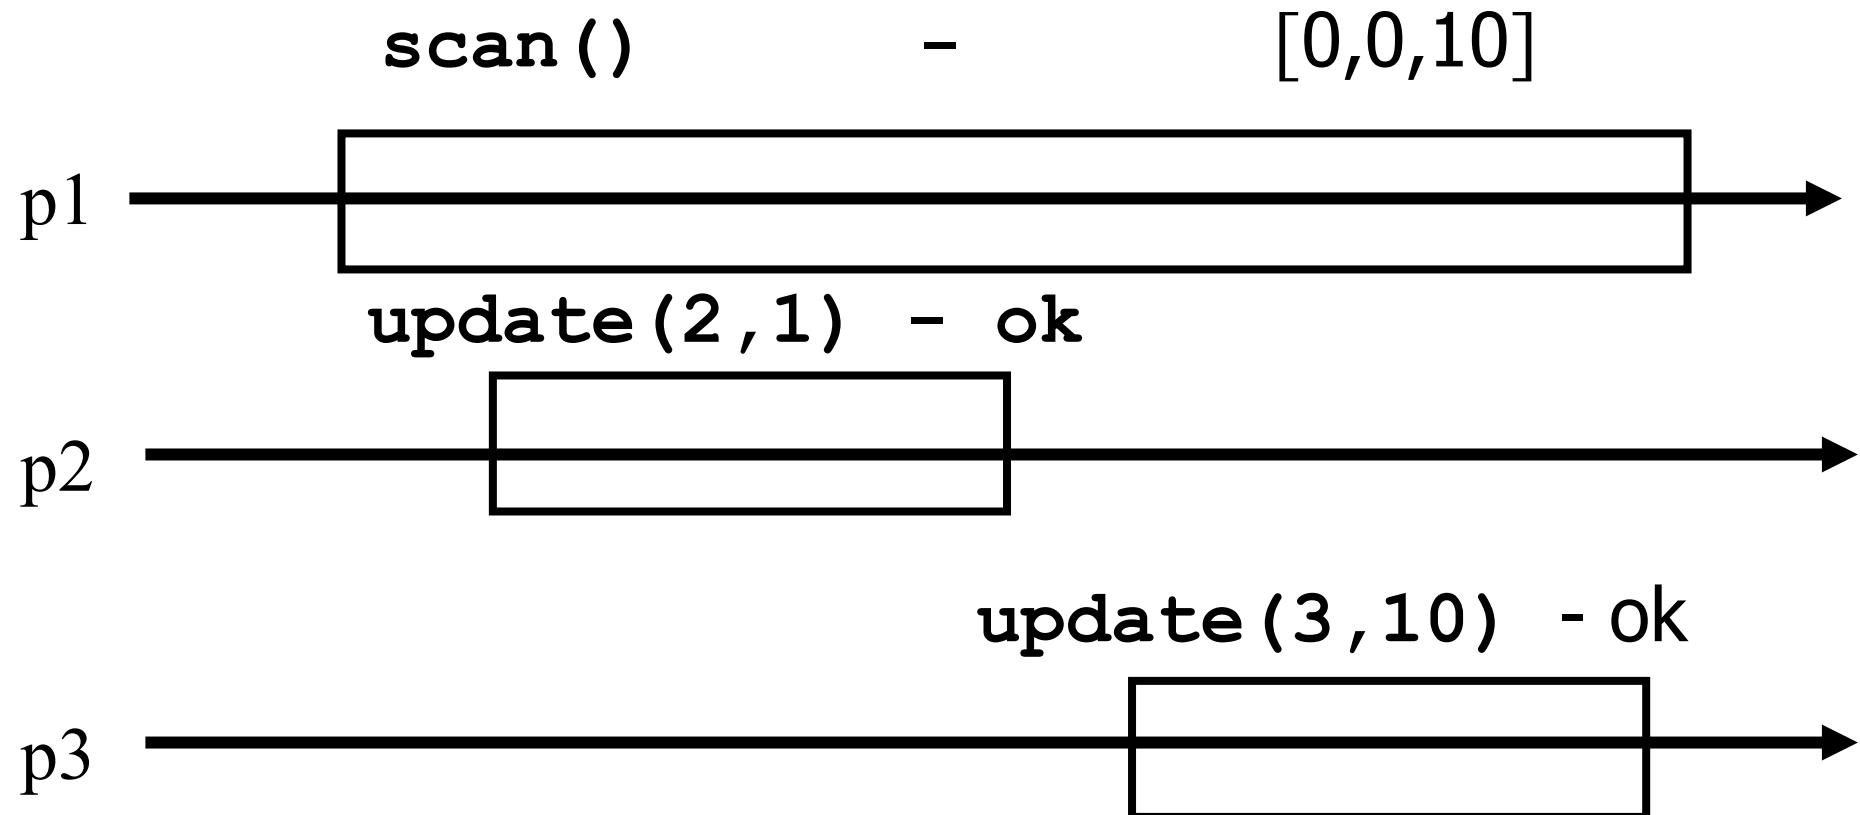

# Atomic execution?

# Atomic execution?

# Atomic execution?

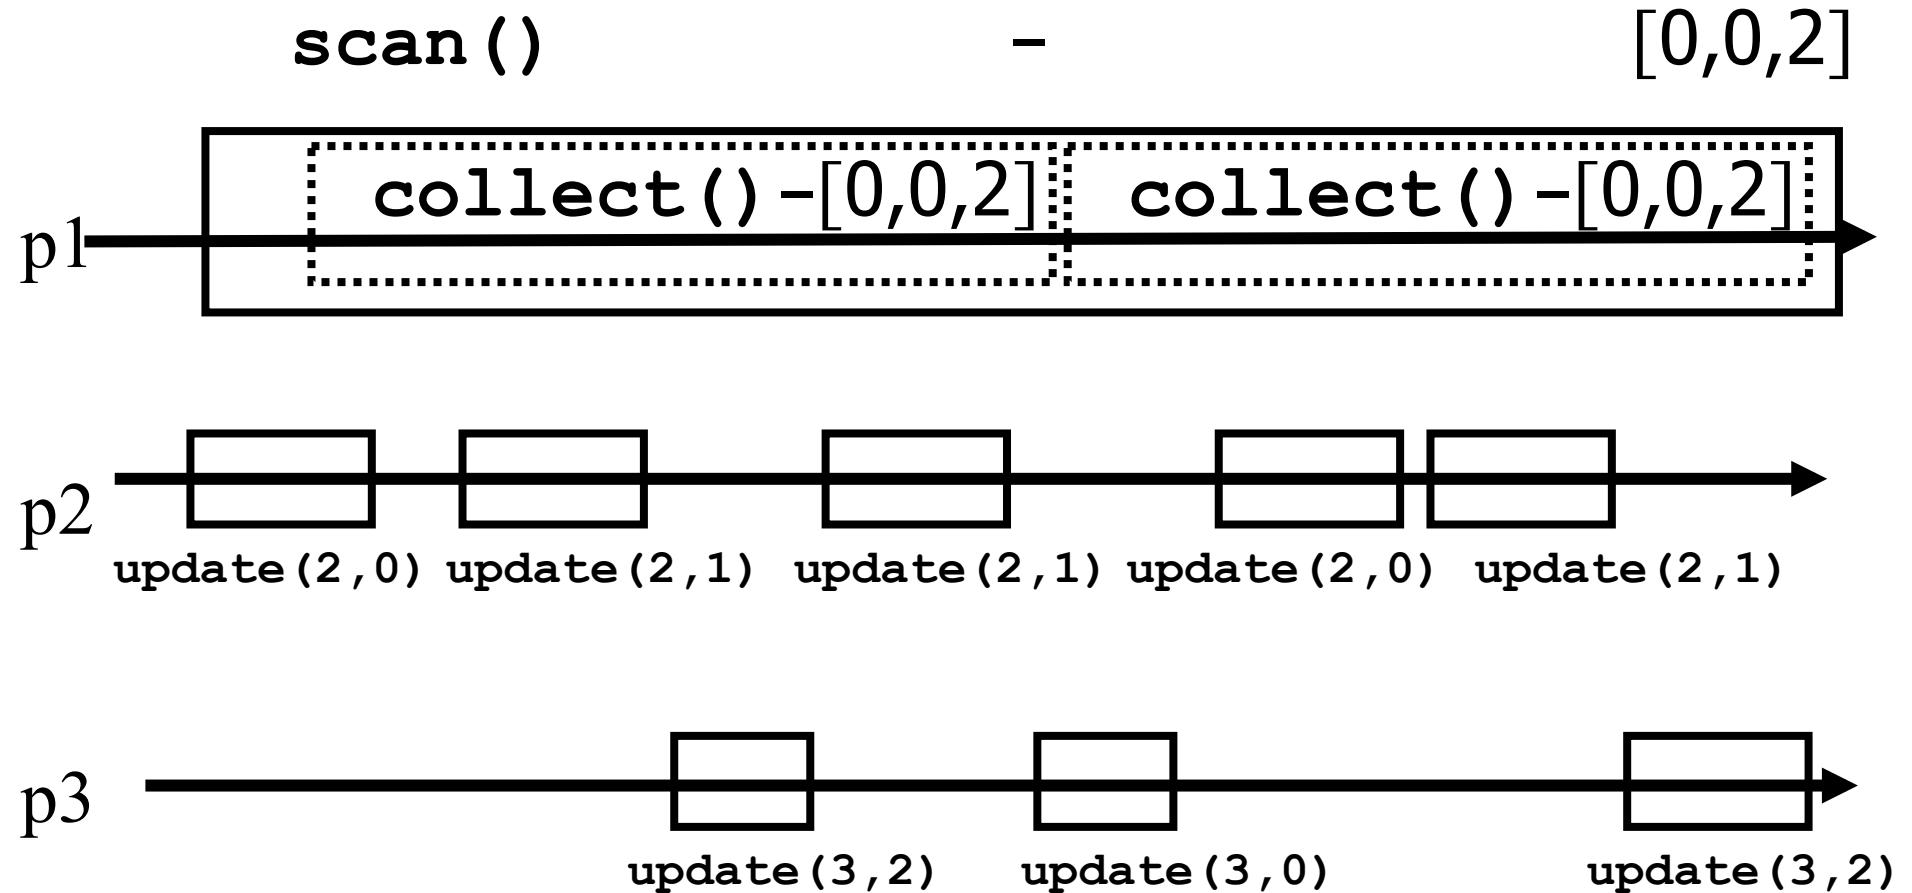

# Non-atomic vs atomic snapshot

- ➊ What we implement here is some kind of ***regular snapshot***.
- ➋ A ***scan*** returns, for every index of the snapshot, the last written values or the value of any concurrent update
- ➌ We call it ***collect***

# Key idea for atomicity

- ➊ To **scan**, a process keeps reading the entire snapshot (i.e., it **collect**), until two results at the *same*
- ➋ This means that the snapshot did not change, and it is safe to return without violating atomicity

# Same value vs. Same timestamp

# Enforcing atomicity

- ➊ The processes share one array of  $N$  registers  $\text{Reg}[1, \dots, N]$ ; each contains a value and a timestamp
- ➋ We use the following operation for modularity
- ➌ ***collect():***
  - ➍ for  $j = 1$  to  $N$  do
    - ➎  $x[j] := \text{Reg}[j].\text{read}();$
  - ➏ return( $x$ )

# Enforcing atomicity (cont'd)

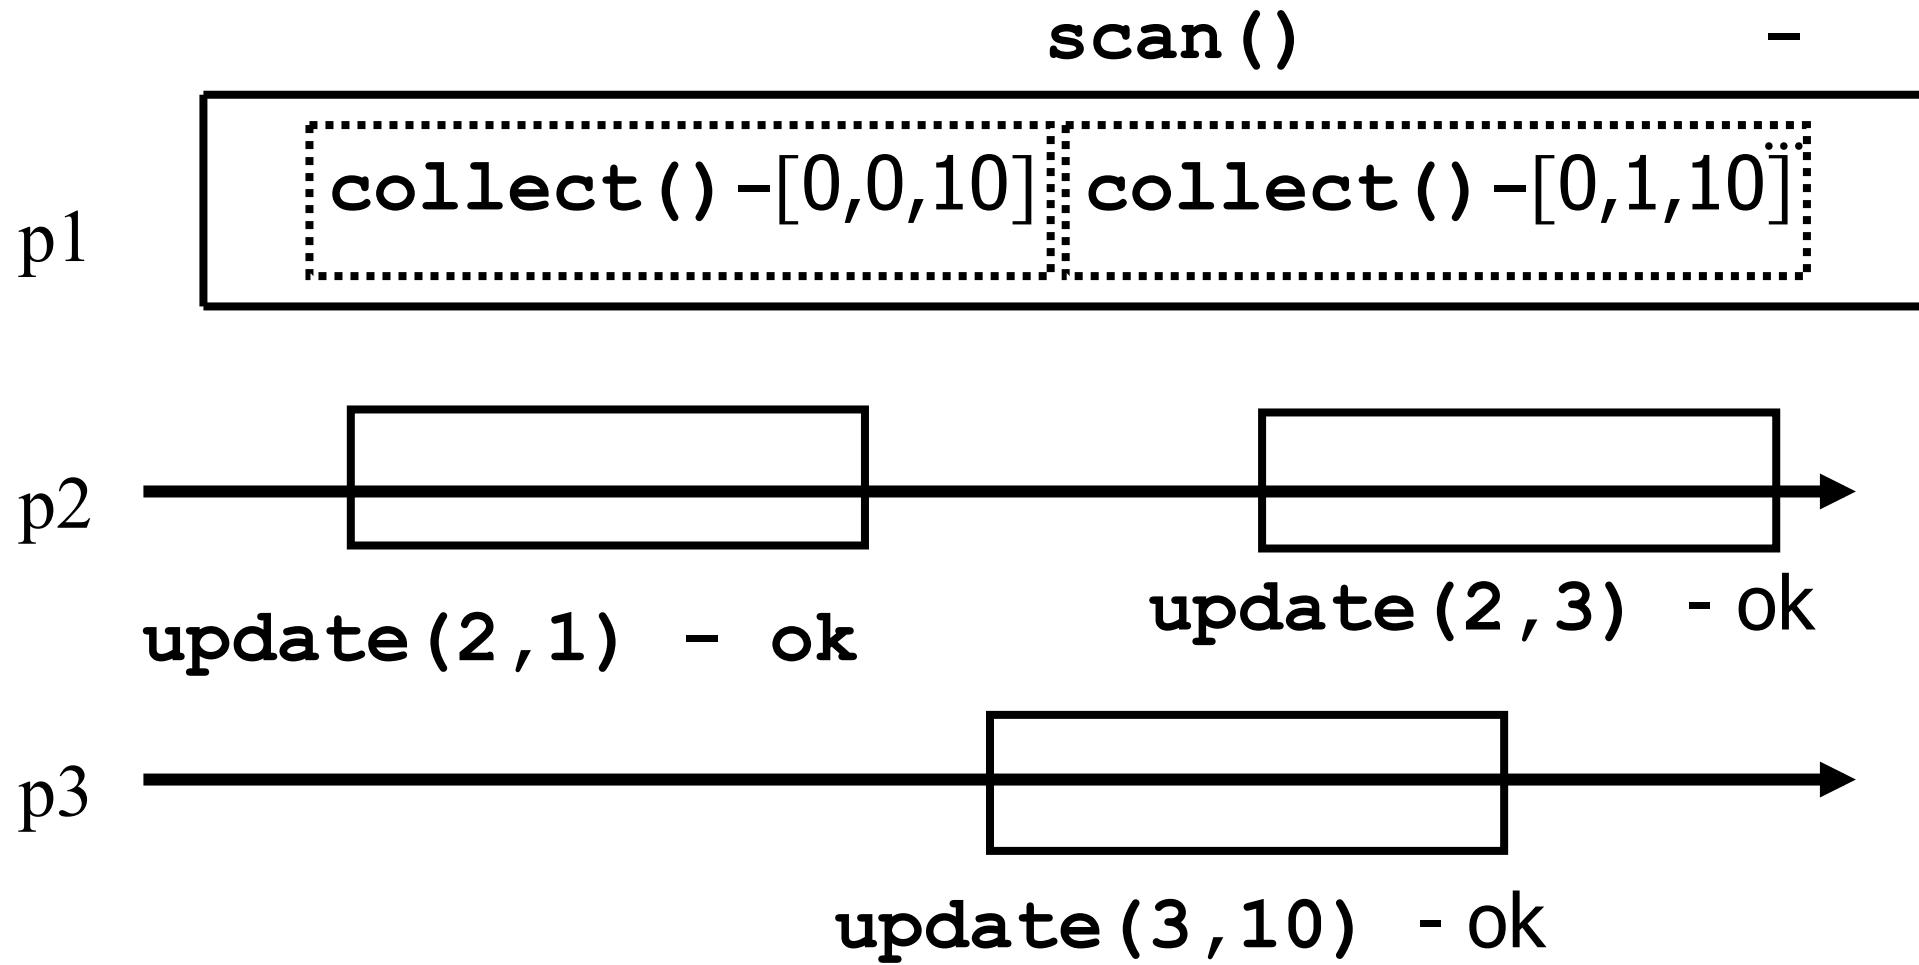

- ➊ ***scan():***

- ➋ temp1 := self.collect();
- ➋ while(true) do
  - ➋ temp2 := self.collect();
  - ➋ if (temp1.tsp = temp2.tsp) then
    - ➋ return (temp1.val)
  - ➋ temp1 := temp2;

- ➋ ***update(i,v):***

- ➋ ts := ts + 1;
- ➋ Reg[i].write(v,ts);
- ➋ return(ok)

# Wait-freedom?

# Key idea for atomicity & wait-freedom

- ➊ The processes share an array of ***registers***  $\text{Reg}[1,..,N]$  that contains each:
  - ➋ a value,
  - ➋ a timestamp, and
  - ➋ a copy of the entire array of values

# Key idea for atomicity & wait-freedom (cont'd)

- To ***scan***, a process keeps collecting and returns a collect if it did not change, or some collect returned by a concurrent ***scan***
  - Timestamps are used to check if the collect changes or if a scan has been taken in the meantime
- To ***update***, a process ***scans*** and writes the value, the new timestamp and the result of the scan

# Snapshot implementation

Every process keeps a local timestamp ts

- ☞ ***update(i,v):***
  - ☞ ts := ts + 1;
  - ☞ Reg[i].write(v,ts,self.scan());
  - ☞ return(ok)

# Snapshot implementation

- ➊ ***scan()*:**
  - ➋  $t_1 := \text{self.collect}(); t_2 := t_1$
  - ➋  $\text{while}(\text{true}) \text{ do}$ 
    - ➋  $t_3 := \text{self.collect}();$
    - ➋  $\text{if } (t_3 = t_2) \text{ then return } (t_3.\text{val});$
    - ➋  $\text{for } j = 1 \text{ to } N \text{ do}$
    - ➋  $\text{if}(t_3[j, 2] \geq t_1[j, 2] + 2) \text{ then}$ 
      - ➋  $\text{return } (t_3[j, 3])$
    - ➋  $t_2 := t_3$

# Possible execution?
