The Limitations of Registers

R. Guerraoui
Distributed Programming Laboratory

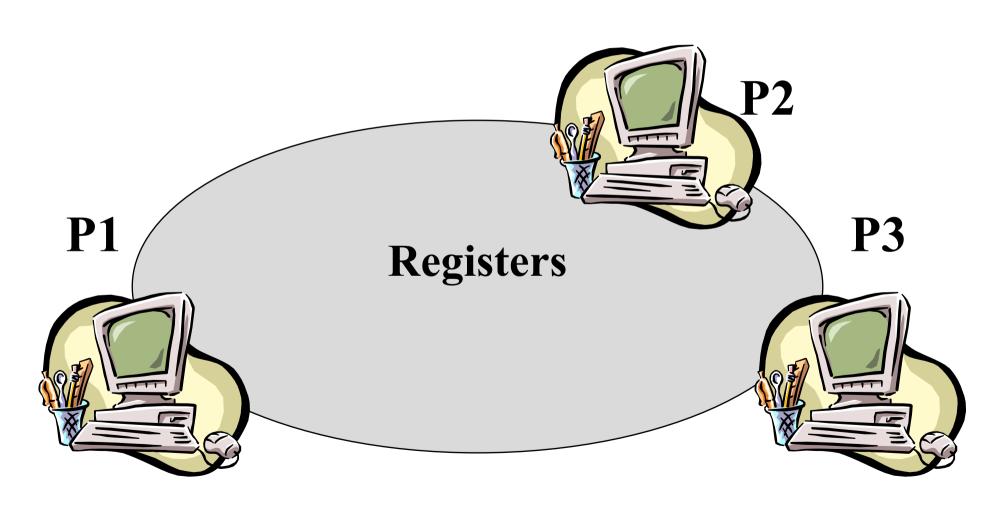

Registers

 Question 1: what objects can we implement with registers? Counters and snapshots (previous lecture)

• **Question 2:** what objects we cannot implement? (this lecture)

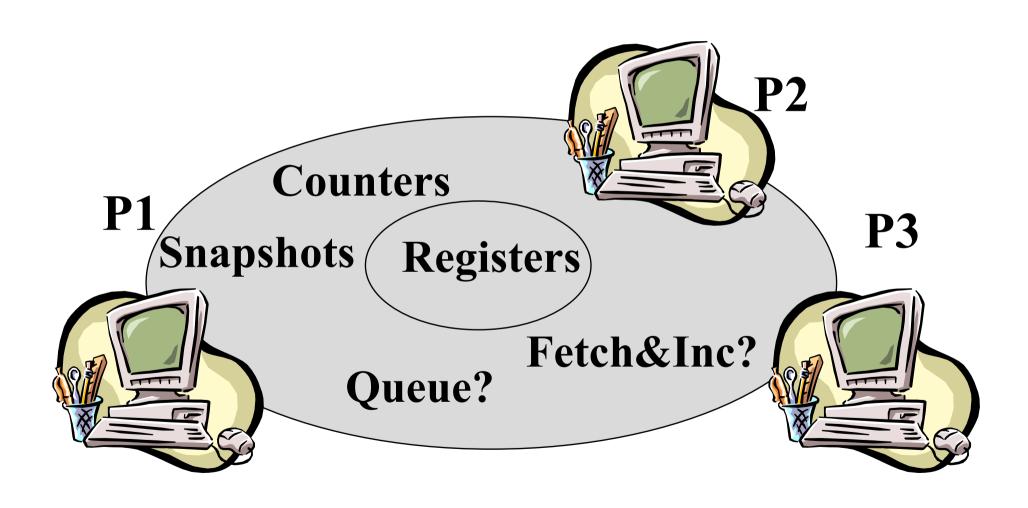

Shared memory model

Shared memory model

Shared memory model

Fetch&Inc

A counter that contains an integer

 Operation fetch&inc() increments the counter and returns the new value

The consensus object

One operation propose() which returns a value.
 When a propose operation returns, we say that the process decides

No two processes decide differently

Every decided value is a proposed value

The consensus object

- Proposition:
 - ✓ Consensus can be implemented among two processes with Fetch&Inc and registers
- Proof (algorithm): consider two processes p0 and p1 and two registers R0 and R1 and a Fetch&Inc C.

2-Consensus with Fetch&Inc

- Uses two registers R0 and R1, and a Fetch&Inc object C (with one fetch&inc() operation that returns its value)
- (NB. The value in C is initialized to 0)
- Process pl:

```
    propose(vI)
    RI.write(vI)
    val := C.fetch&inc()
    if(val = 1) then
    return(vI)
    else return(R{1-I}.read())
```

Impossibility [FLP85,LA87]

 Proposition: No asynchronous deterministic algorithm implements consensus among two processes using only registers

 Corollary: No algorithm implements Fetch&Inc among two processes using only registers

Queue

 The queue is an object container with two operations: enq() and deq()

- Can we implement a (atomic wait-free) queue?

2-Consensus with queues

Uses two registers R0 and R1, and a queue Q Q is initialized to {winner, loser}

Process pl:

```
propose(vI)
  RI.write(vI)
  item := Q.dequeue()
  if item = winner return(vI)
  return(R{1-I}.read())
```

Correctness

Proof (algorithm):

- (wait-freedom) by the assumption of a wait-free register and a wait-free queue plus the fact that the algorithm does not contain any wait statement
- (validity) If pl dequeues winner, it decides on its own proposed value. If pl dequeues loser, then the other process pJ dequeued winner before. By the algorithm, pJ has previously written its input value in RJ. Thus, pl decides on pJ's proposed value;
- (agreement) if the two processes decide, they decide on the value written in the same register.

More consensus implementations

- A Test&Set object maintains binary values x, init to 0, and y; it provides one operation: test&set()
 - ✓ Sequential spec:

```
√ test&set() {y := x; x: = 1; return(y);}
```

- A Compare&Swap object maintains a value x, init to \(\perpsilon\), and provides one operation: compare&swap(v,w);
 - ✓ Sequential spec:
 - c&s(old,new) {if x = old then x := new; return(x)}

2-Consensus with Test&Set

Uses two registers R0 and R1, and a Test&Set object T

Process pl:

```
    propose(vl)
    RI.write(vl)
    val := T.test&set()
    if(val = 0) then
    return(vl)
    else return(R{1-I}.read())
```

N-Consensus with C&S

Uses a C&S object C

Process pl:

```
    propose(vl)
    val := C.c&s(⊥,vl)
    if(val = ⊥) then
    return(vl)
    else return(val)
```

Impossibility [FLP85,LA87]

- Proposition: there is no asynchronous
 deterministic algorithm that implements consensus
 among two processes using only registers
- Corollary: there is no algorithm that implements a queue (Fetch&Inc,...) among two processes using only registers

Registers

 Question 1: what objects can we implement with registers? Counters and snapshots (previous lecture)

Question 2: what objects we cannot implement?
 All objects that (together with registers) can implement consensus (this lecture)

Impossibility (Proof)

- Proposition: there is no algorithm that implements consensus among two processes using only registers
- Proof (by contradiction): consider two processes p0 and p1 and any number of registers, R1..Rk..

Assume that a consensus algorithm A for p0 and p1 exists.

Elements of the model

 A configuration is a global state of the distributed system

 A new configuration is obtained by executing a step on a previous configuration: the step is the unit of execution

Elements of the model

 The adversary decides which process executes the next step and the algorithm deterministically decides the next configuration based on the current one

What is distributed computing? A game

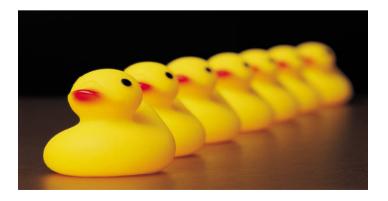

A game between an adversary and a set of processes

The adversary decides which process goes next

The processes take steps

Elements of the model

 The adversary decides which process executes the next step and the algorithm deterministically decides the next configuration based on the current one

Elements of the model

- Schedule: a sequence of steps represented by process ids
- The schedule is chosen by the system
- An asynchronous system is one with no constraint on the schedules: any sequence of process ids is a schedule

Consensus

 The algorithm must ensure that agreement and validity are satisfied in every schedule

 Every process that executes an infinite number of steps eventually decides

Impossibility (elements)

- (1) a (initial) configuration C is a set of (initial) values of p0 and p1 together with the values of the registers: R1..Rk,..;
- (2) a step is an elementary action executed by some process pl: it consists in reading or writing a value in a register and changing pl's state according to the algorithm A;
- (3) a schedule S is a sequence of steps; S(C) denotes the configuration that results from applying S to C.

Impossibility (elements)

Consider u to be 0 or 1; a configuration C is u-valent if, starting from C, no matter how the processes behave, no decision other than u is possible

We say that the configuration is univalent.
 Otherwise, the configuration is called bivalent

$$\begin{array}{c|cccc} W(X) & R() -> Y & Return(0) \\ \hline P0(0) & & & & \\ \hline RI & RJ & \\ \hline W(Z) & W(V) & Return(0) \\ \hline P1(0) & & & & \\ \hline RK & RL & \\ \hline \end{array}$$

$$\begin{array}{c|cccc} W(X) & R() -> Y & Return(1) \\ \hline P0(1) & & & & \\ \hline RI & RJ & \\ \hline W(Z) & W(V) & Return(1) \\ \hline P1(1) & & & & \\ \hline RK & RL & \\ \hline \end{array}$$

$$W(X) \qquad R()\rightarrow Y \qquad Return(1/0)$$

$$P0(1) \qquad \qquad | \qquad \qquad | \qquad \qquad |$$

$$RI \qquad RJ \qquad \qquad |$$

$$W(Z) \qquad W(V) \qquad Return(1/0)$$

$$P1(0) \qquad | \qquad \qquad | \qquad \qquad |$$

$$RK \qquad RL$$

Impossibility (structure)

Lemma 1: there is at least one initial bivalent configuration

 Lemma 2: given any bivalent configuration C, there is an arbitrarily long schedule S(C) that leads to another bivalent configuration

The conclusion

 Lemmas 1 and 2 imply that there is a configuration C and an *infinite* schedule S such that, for any prefix S' of S, S'(C) is bivalent.

 In infinite schedule S, at least one process executes an infinite number of steps and does not decide

A contradiction with the assumption that A implements consensus.

The initial configuration C(0,1) is bivalent

Proof: consider C(0,0) and p1 not taking any step: p0 decides 0; p0 cannot distinguish C(0,0) from C(0,1) and can hence decides 0 starting from C(0,1); similarly, if we consider C(1,1) and p0 not taking any step, p1 eventually decides 1; p1 cannot distinguish C(1,1) from C(0,1) and can hence decides 1 starting from C(0,1). Hence the bivalency.

Given any bivalent configuration C, there is an arbitrarily long schedule S such that S(C) is bivalent

Proof (by contradiction): let S be the schedule with the maximal length such as D=S(C) is bivalent; p0(D) and p1(D) are both univalent: one of them is 0-valent (say p0(D)) and the other is 1-valent (say p1(D))

■ Proof (cont'd): To go from D to p0(D) (vs p1(D)) p0 (vs p1) accesses a register; the register must be the same in both cases; otherwise p1(p0(D)) is the same as p0(p1(D)): in contradiction with the very fact that p0(D) is 0-valent whereas p1(D) is 1-valent

■ Proof (cont'd): To go from D to p0(D), p0 cannot read R; otherwise R has the same state in D and in p0(D); in this case, the registers and p1 have the same state in p1(p0(D)) and p1(D); if p1 is the only one executing steps, then p1 eventually decides 1 in both cases: a contradiction with the fact that p0(D) is 0-valent; the same argument applies to show that p1 cannot read R to go from D to p1(D)

Thus both p0 and p1 write in R to go from D to p0(D) (resp., p1(D)). But then p0(p1(D))= p0(D) (resp. p1(p0(D))= p1(D)) --- a contradiction.

The conclusion (bis)

Lemmas 1 and 2 imply that there is a configuration C and an *infinite* schedule S such that, for any prefix S' of S, S'(C) is bivalent.

In infinite schedule S, at least one process executes an infinite number of steps and does not decide

A contradiction with the assumption that A implements consensus.
