

Distributed systems

Total Order Broadcast

Prof R. Guerraoui Distributed Programming Laboratory

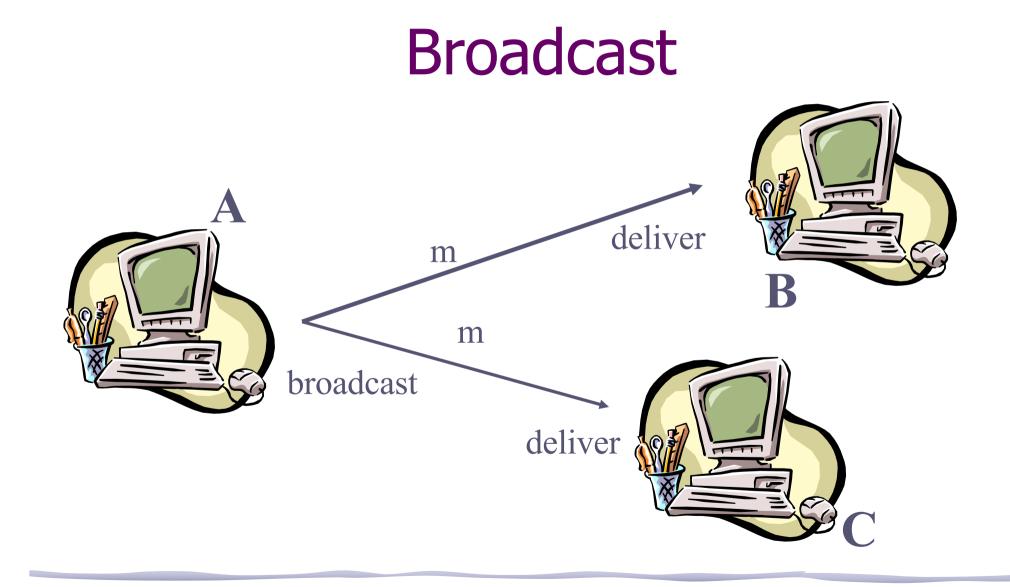

Overview

Intuitions: what is total order broadcast?

Specifications of total order broadcast

Consensus-based total order algorithm

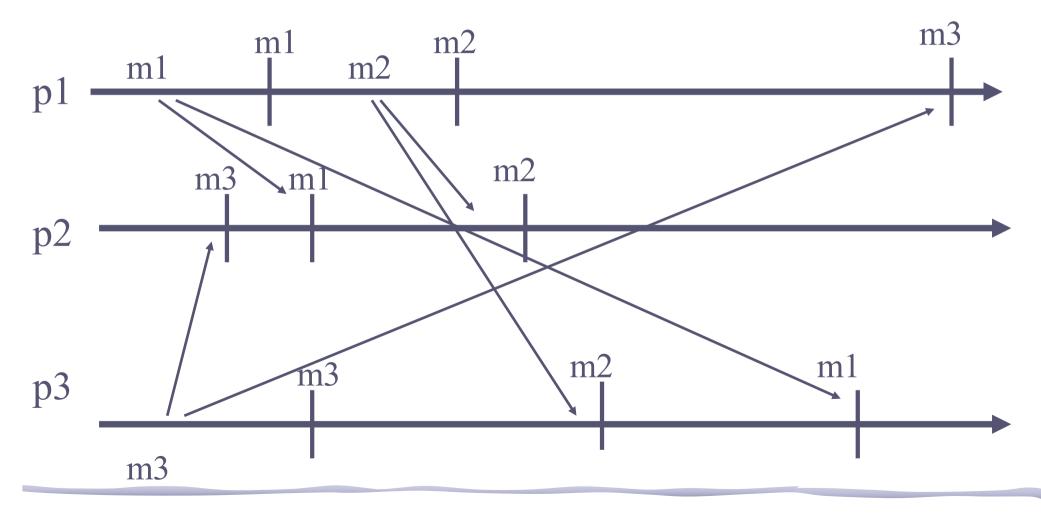

Intuitions (1)

- In *reliable* broadcast, the processes are free to deliver messages in any order they wish
- In *causal* broadcast, the processes need to deliver messages according to some order (causal order)
- The order imposed by causal broadcast is however partial: some messages might be delivered in different order by the processes

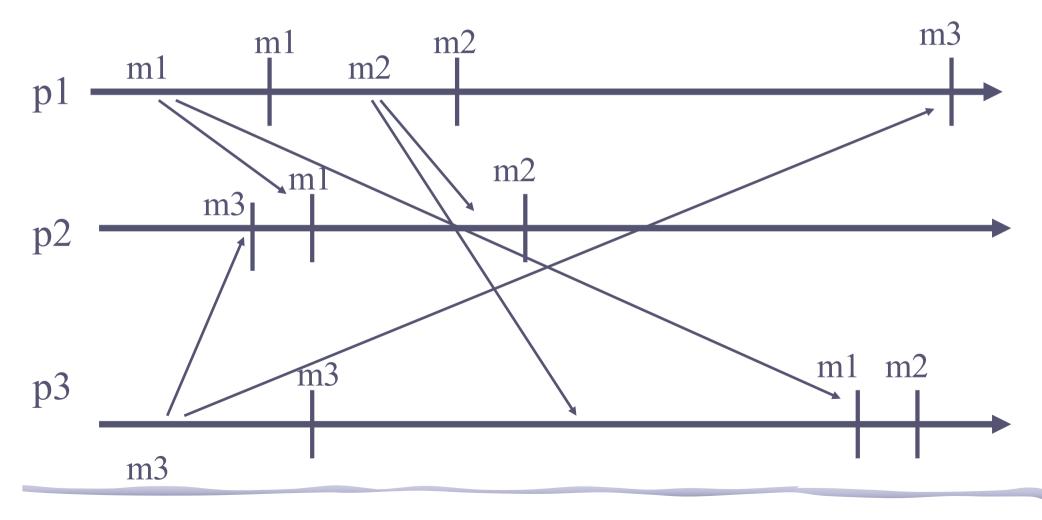

Reliable Broadcast

Causal Broadcast

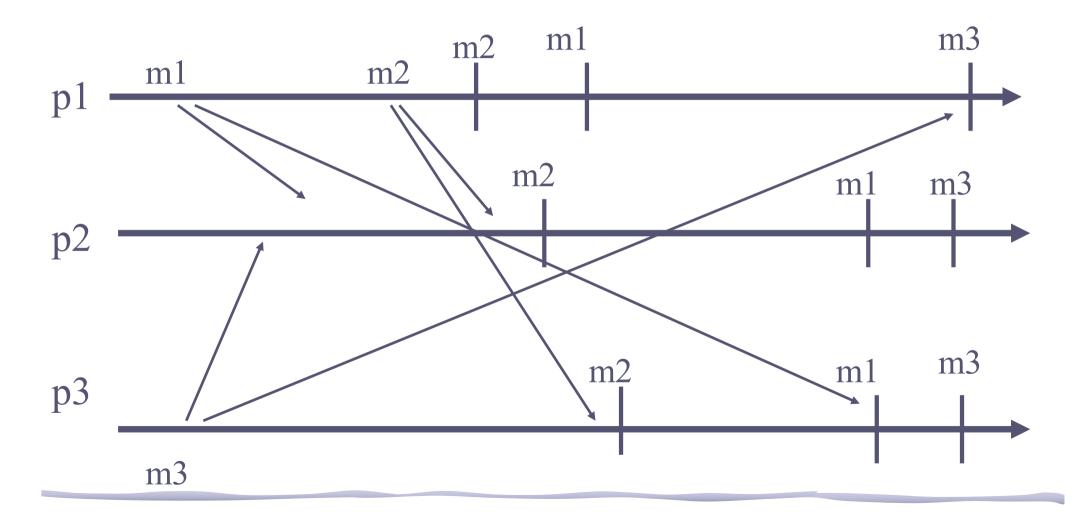

Intuitions (2)

- In total order broadcast, the processes must deliver all messages according to the same order (i.e., the order is now total)
- Note that this order does not need to respect causality (or even FIFO ordering)
- Total order broadcast can be made to respect causal (or FIFO) ordering

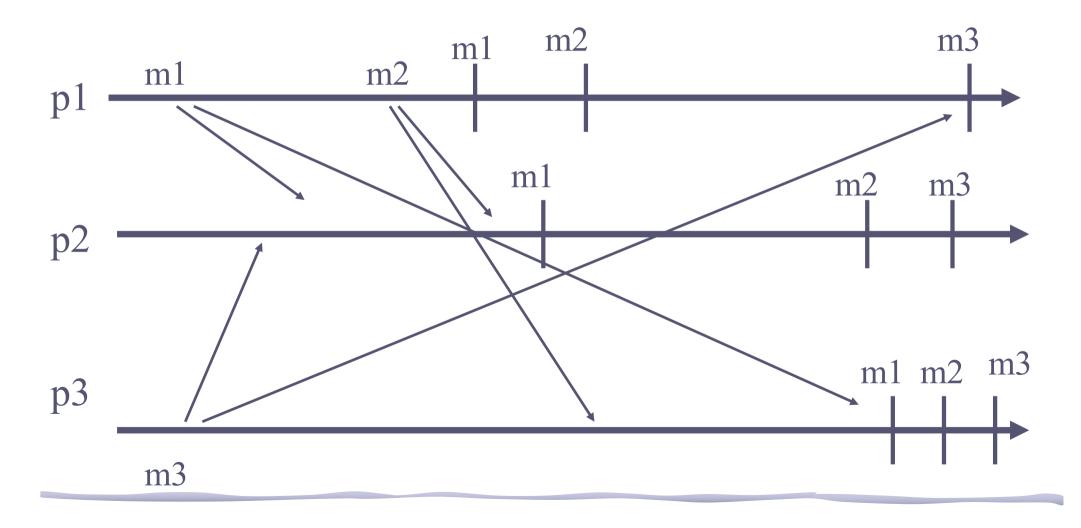

Total Order Broadcast (I)

Total Order Broadcast (II)

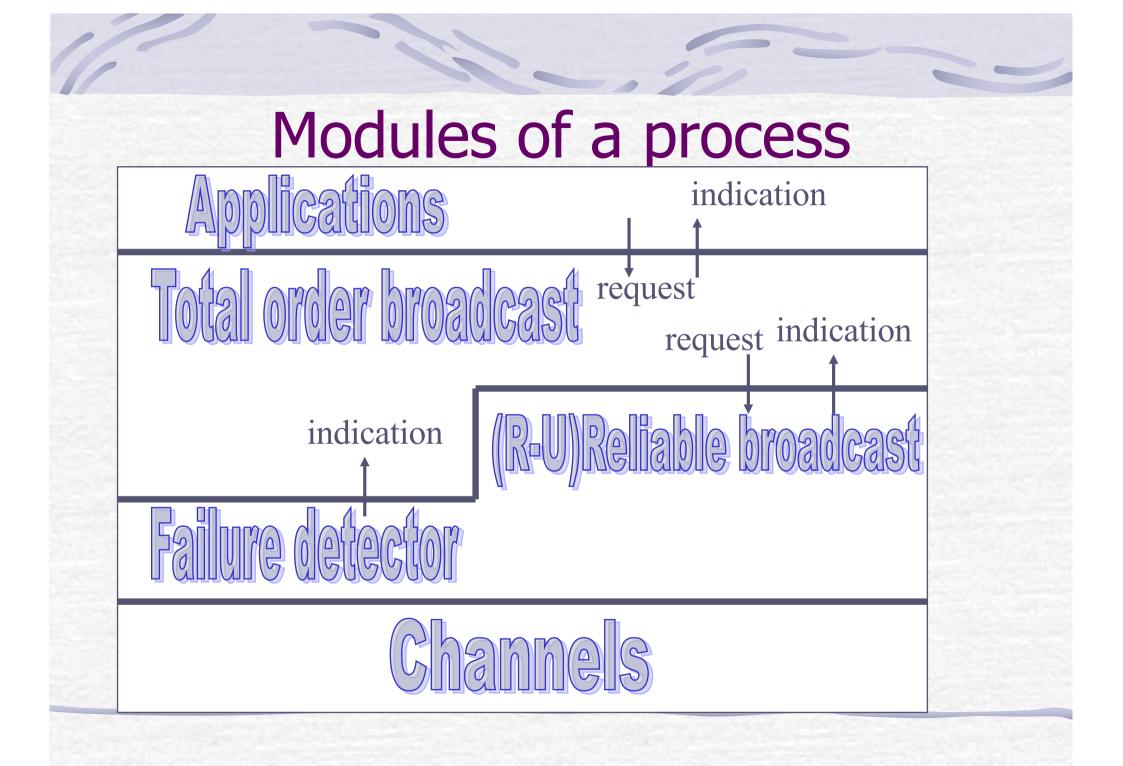

Intuitions (3)

A replicated service where the replicas need to treat the requests in the *same order* to preserve consistency

(we talk about state machine replication)

A notification service where the subscribers need to get notifications in the same order

Overview

Intuitions: what is total order broadcast?

Specifications of total order broadcast

Consensus-based algorithm

Total order broadcast (tob)

Events

- Request: <toBroadcast, m>
- Indication: <toDeliver, src, m>
- Properties:
 - RB1, RB2, RB3, RB4
 - Total order property

Specification (I)

Validity: If pi and pj are correct, then every message broadcast by pi is eventually delivered by pj

- *No duplication:* No message is delivered more than once
- *No creation:* No message is delivered unless it was broadcast
- *(Uniform) Agreement:* For any message m. If a correct (any) process delivers m, then every correct process delivers m

Specification (II)

(Uniform) Total order.

- Let m and m' be any two messages.
- Let pi be any (correct) process that delivers m without having delivered m'
- Then no (correct) process delivers m' before m

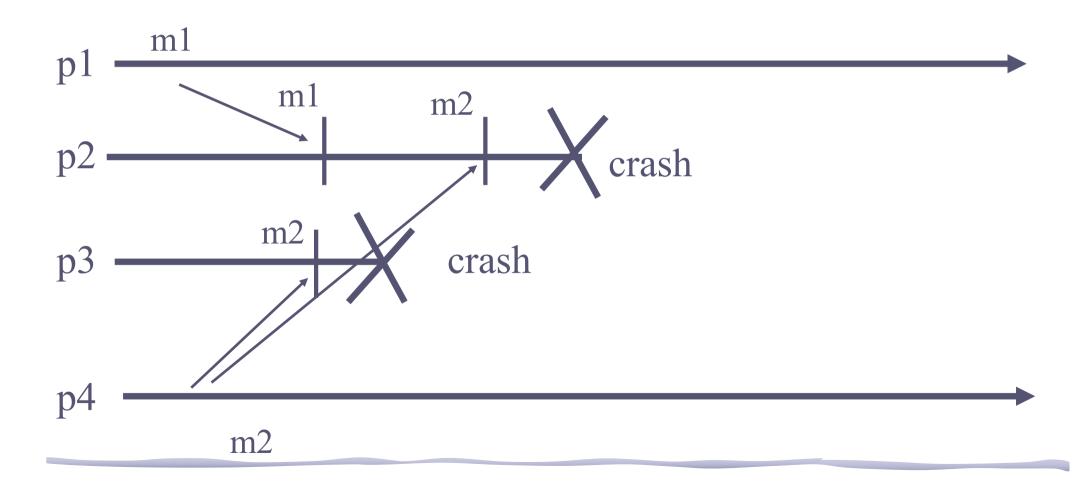

Specifications

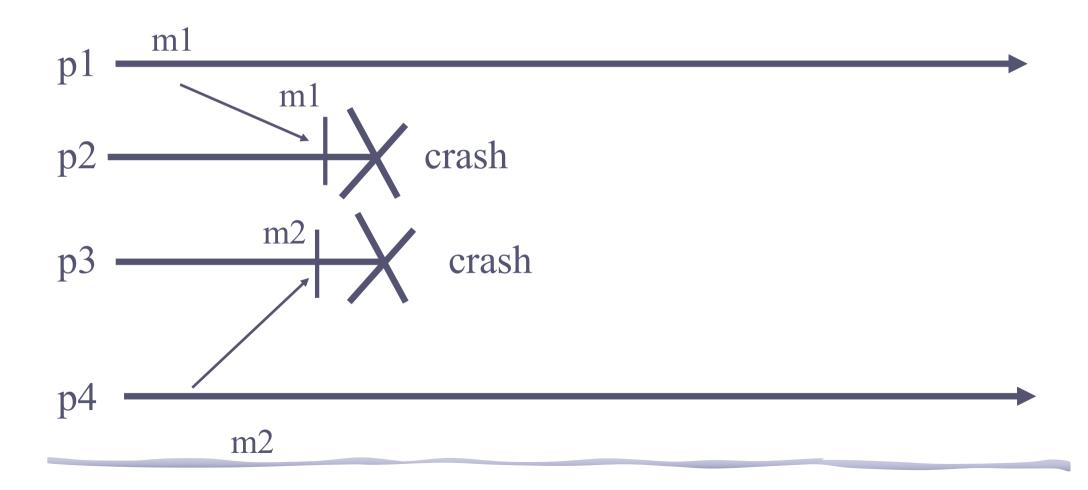

Note the difference with the following properties:

- Let pi and pj be any two correct (any) processes that deliver two messages m and m'. If pi delivers m' before m, then pj delivers m' before m.
- Let pi and pj be any two (correct) processes that deliver a message m. If pi delivers a message m' before m, then pj delivers m' before m.

Overview

- Intuitions: what total order broadcast can bring?
- Specifications of total order broadcast
- Consensus-based algorithm

(Uniform) Consensus

In the (uniform) consensus problem, the processes propose values and need to agree on one among these values

C1. Validity: Any value decided is a value proposed

C2. (Uniform) Agreement: No two correct (any) processes decide differently

C3. Termination: Every correct process eventually decides

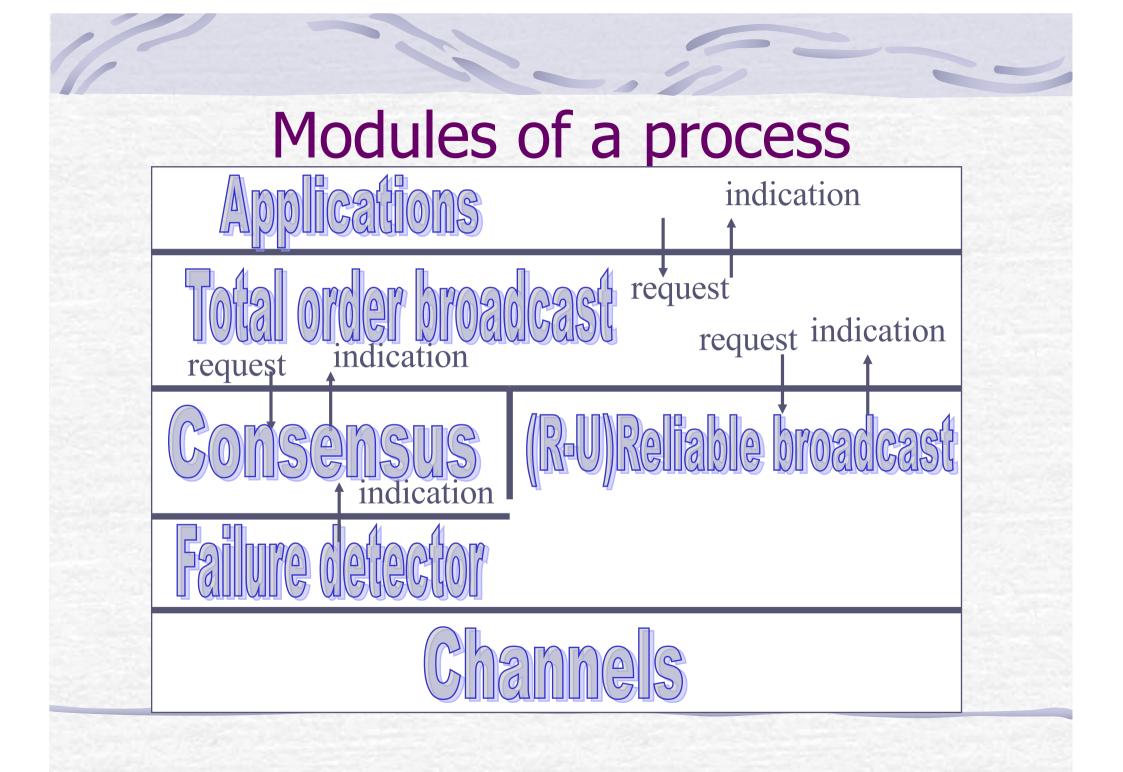

C4. Integrity: Every process decides at most once

Consensus

Events

- Request: <Propose, v>
- Indication: <Decide, v'>
- Properties:
 - *C1, C2, C3, C4*

Algorithm

- *r* **Implements:** TotalOrder (to).
- Vses:
 - ReliableBroadcast (rb).
 - Consensus (cons);
- r upon event < Init > do
 - \checkmark unordered: = delivered: = \varnothing ;
 - wait := false;

sn := 1;

Algorithm (cont'd)

- upon event < toBroadcast, m> do
 - trigger < rbBroadcast, m>;
- ✓ upon event <rbDeliver,sm,m> and (m ∉ delivered)
 do
 - unordered := unordered U {(sm,m)};
- *upon* (unordered $\neq \emptyset$) and not(wait) **do**
 - wait := true:
 - r trigger < Propose, unordered>sn;

Algorithm (cont'd)
upon event <Decide,decided>sn do
unordered := unordered \ decided;
ordered := deterministicSort(decided);
for all (sm,m) in ordered:
 trigger < toDeliver,sm,m>;

delivered := delivered U {m};

wait := false;

Equivalences

- 1. One can build consensus with total order broadcast
- 2. One can build total order broadcast with consensus and reliable broadcast

Therefore, consensus and total order broadcast are equivalent problems in a system with reliable channels
